1 Question 1: CLRS Problem 7.1

1.1 a

This is certain concerning the *Randomized* procedure, the probability of any index i is chosen from $[0, n-1]$is:
$Pr(pivot = i) = \frac{1}{n}$
$E(X_i) = 1 * Pr(pivot = i) + 0 * Pr(pivot \neq i) = \frac{1}{n}$

1.2 b

It is certain that if ith element is chosen as pivot, $Random - Parition$ cost $\Theta(n)$ time, and it will call $QuickSort[1, q-1], QuickSort[q+1, n]$ recursively.
Concerning only the first $Parition$, this would be the result:
$E(T(n)) = \Sigma_{i=1}^{n} Pr(pivot = i)(T(i-1) + T(n-i) + \Theta(n))$
$= \Sigma_{i=1}^{n} X_i(T(i-1) + T(n-i) + \Theta(n))$

1.3 c

Concerning $X_i = \frac{1}{n}$
$E(T(n)) = \Sigma_{i=1}^{n} \frac{1}{n}(T(i-1) + T(n-i) + \Theta(n))$
$= \Sigma_{i=1}^{n} \frac{1}{n} T(i-1) + \Sigma_{i=1}^{n} \frac{1}{n} T(n-i) + \Sigma_{i=1}^{n} \frac{1}{n} \Theta(n)$
$= \frac{2}{n} \Sigma_{i=1}^{n-1} T(i) + \Theta(n)$

1.4 d

$\Sigma_{k=2}^{n-1} klgk$
$\leq lg\frac{n}{2} \Sigma_{k=2}^{\frac{n}{2}} k + lgn \Sigma_{k=\frac{n}{2}}^{n-1} k$
$= lgn \Sigma_{k=2}^{n-1} k - lg2 \Sigma_{k=2}^{\frac{n}{2}} k$
$= lgn \frac{(n+1)(n-2)}{2} - \frac{(\frac{n}{2}+2)(\frac{n}{2}-1)}{2}$
$\leq lgn \frac{n^2}{2} - \frac{n^2}{8}$
by Calculus, we have:
$(\frac{1}{2}x^2 lgx - \frac{1}{4}x^2)|_1^{n-1} \leq E(T(n)) \leq (\frac{1}{2}x^2 lgx - \frac{1}{4}x^2)|_2^{n}$

1.5 e

Proof of $E(T(n)) = O(nlgn)$:
Assume that $\forall k \in [1, n-1], \exists c, E(T(k)) \leq cklgk - \Theta(k)$
For $k = n, E(T(n)) \leq \frac{n}{2}c(lgn\frac{n^2}{2} - \frac{n^2}{4} - \Theta(n^2)) + \Theta(n) \leq cnlgn - \Theta(n)$
Proof of $E(T(n)) = \Omega(nlgn)$:
Assume that $\forall k \in [1, n-1], \exists c, E(T(k)) \geq cklgk + \Theta(k)$
For $k = n, E(T(n)) \geq \frac{n}{2}c(lgn\frac{(n-1)^2}{2} - \frac{(n-1)^2}{4} + \Theta(n^2)) + \Theta(n) \geq cnlgn + \Theta(n)$
$\rightarrow E(T(n)) = \Theta(nlgn)$

2 Question 2: CLRS Problem 7.5

2.0.1 a

From counting Theorem, it could be noticed that:
$p_i = \frac{(i-1)(n-i)}{C_n^3} = \frac{6(i-1)(n-i)}{n(n-1)(n-2)}$

2.0.2 b

$Pr(i = medium)(normal) = \frac{1}{n}$
$Pr(i = medium)(3part) = \frac{6(\frac{1}{2}n-1)(n-\frac{1}{2}n)}{n(n-1)(n-2)} = \frac{3}{2}\frac{1}{n}$
$Pr(3part) - Pr(normal) = \frac{1}{2}\frac{1}{n}$

2.0.3 c

Consider $f_{diff} = \int_{\frac{n}{3}}^{\frac{2}{3}n}(\frac{6(i-1)(n-i)}{n(n-1)(n-2)} - \frac{1}{n})di$
$= \frac{(-2i^3+3(n+1)i^2-6ni-(n-1)(n-2)i)|_{i=\frac{1}{3}n}^{i=\frac{2}{3}n}}{n(n-1)(n-2)}$
$lim_{n\rightarrow\infty}f_{diff} = \frac{4}{27}$

2.0.4 d

Consider we are so lucky that each partition we choose the median:
In the Iteration tree, we have:
$T(n) = \begin{cases} c & n = 1 \\ 2T(\frac{1}{2}n) + n & n > 1 \end{cases}$
The $\Omega(nlgn)$ is kept even in best case.

3 Question 3: Illustrate COUNTING-SORT

See Figure 1

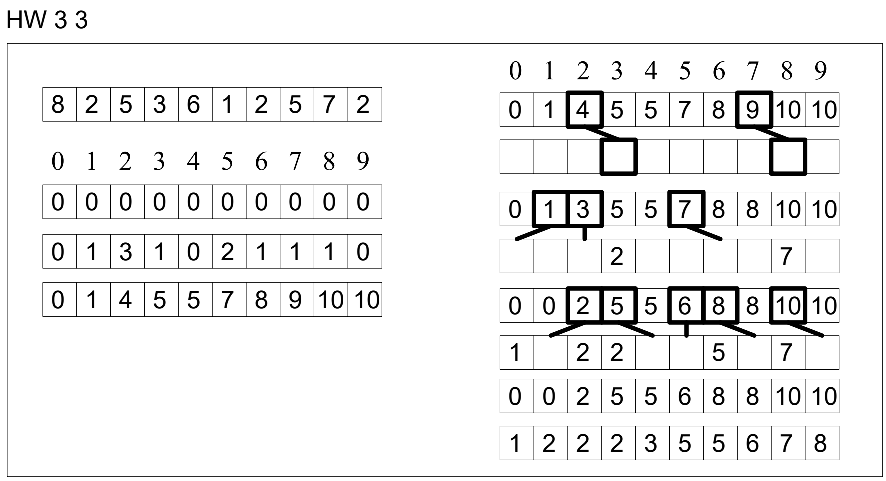

Figure 1: Question 3

4 Question 4: CLRS Exercise 8.2-4

Consider a trim version of counting sort, build the C map up and query directly:

Counting-sort-trim(A, k)

$C[]$
for $i = 0$ **to** k
    $C[i] = 0$
for $j = 1$ **to** $A.length$
    $C[A[j]] + +$
for $m = 1$ **to** k
    $C[m] + = C[m-1]$
return $C[m]$

Direct-Quert(A, k, a, b)

$C =$ Counting-sort-trim(A, k)
if $a < 1$
    return $C[b]$
else return $C[b] - C[a-1]$

5 Question 5: CLRS Exercise 8.3-4

First, with $O(n)$ time: convert n numbers k_{10} into k_n which has 3 digits. Second, with $O(d(n+n))$ time ($Lemma$8.3): Radix sort n 3-digit numbers with each digits take up to n possible values.

```
digitsConvert(X)
result[]
for i = 2 downto 0
    result[i] = X/n^i
    X = X mod n^i
return result
```

```
sort(A, x)
result[]
for each S in A
    S = digitsConvert(S)
radix-sort(A, x)
```

6 Question 6: CLRS Problem 9.1

6.1 a

Sorting: MERGE-SORT(A) in worst case $O(nlgn)$
Query: CALL-BY-RANK(A, k) i times in worst case $O(i)$, here we assume manipulating $O(n)$ space cost $O(n)$ time.

6.2 b

Building: BUILD-MAP-HEAP(A) in worst case $O(n)$
Query: calling EXTRA-MAX(A, k) i times in worst case $O(ilgn)$

6.3 c

Selecting: SELECT(A, i) in worst case $O(n)$
Sorting: MERGE-SORT$(A^{'})$ in worst case $O(ilgi)$

7 Question 7: CLRS Problem 11.2

7.1 a

Consider for a ball i fall into a specific bucket $Pr(i) = \frac{1}{n}$
Then consider Binomial Distribution, $Pr(k) = C_n^k Pr(i)^k (1 - Pr(i))^{n-k}$

7.2 b

Consider random picking a slot, the probability of that slot is maximum is $Pr_{max} = \frac{1}{n}$, and it contains k elements Q_k. for conditional probability, we have:
$P_k = Pr_{i=k|max} = \frac{Pr(i=k \cap max)}{Pr_{max}} \leq \frac{Pr(i=k)}{Pr_{max}} = nQ_k$

7.3 c

Proof:
$Q_k = (\frac{1}{n})^k (\frac{n-1}{n})^{n-k} C_n^k$
$= \frac{(n-1)^{n-k}}{n^n} \frac{\Pi_0^{k-1} n-k}{k!}$
$\leq \frac{n^n}{n^n} \frac{1}{k!}$
$= \frac{e^k}{k^k} \frac{1}{k^{\frac{1}{2}}(1+\Theta(\frac{1}{n}))}$
$\leq \frac{e^k}{k^k}$

7.4 d

Proof for Q_{k_0}:
$Q_{k_0} = \frac{e^{(\frac{clgn}{lglgn})}}{(\frac{clgn}{lglgn})^{\frac{clgn}{lglgn}}}$
$= \frac{n^{\frac{clg\frac{e}{c}}{lglgn}}}{\frac{n^c}{n^{\frac{clglglgn}{lglgn}}}} = n^{\frac{clg\frac{e}{c}+clglglgn}{lglgn}-c}$
It would not take effort to notice that since $lim_{n\to\infty} \frac{clg\frac{e}{c}+clglglgn}{lglgn} = 0$
$\forall c > 3+\epsilon, Q_{k_0} = O(\frac{1}{n^3})$
And $P_k \leq nQ_k \to P_k = O(\frac{1}{n^2})$

7.5 e

$E(M) = \Sigma_{M=1}^{n} MPr(M) < nPr(M > \frac{clgn}{lglgn}) + \frac{clgn}{lglgn} Pr(M \leq \frac{clgn}{lglgn})$
A stronger conclusion to note:
$E(M) = \Sigma_{M=1}^{n} MPr(M) < MPr(M > \frac{clgn}{lglgn}) + \frac{clgn}{lglgn} Pr(M \leq \frac{clgn}{lglgn})$
$\leq \int_{\frac{clgn}{lglgn}}^{\infty} \frac{1}{n} dn + 1 * \frac{clgn}{lglgn}$
$= lg(\frac{clgn}{lglgn}) + \frac{clgn}{lglgn}$
$= O(\frac{clgn}{lglgn})$
